

## CCD MINIMA FOR SELECTED ECLIPSING BINARIES IN 2021

NELSON, ROBERT H.<sup>1,2</sup>

<sup>1</sup> Mountain Ash Observatory, 1393 Garvin Street, Prince George, BC, Canada, V2M 3Z1 e-mail: bob.nelson@shaw.ca

<sup>2</sup> Desert Blooms Observatory, Benson, AZ, U.S.A.

**Abstract:** A total of 214 CCD determinations of times of minimum for selected eclipsing binaries occurring in 2021 are presented. These were obtained at either Mountain Ash Observatory in Prince George, BC, Canada or Desert Blooms Observatory in Benson, AZ, USA.

### 1 Introduction

This is the 24th annual report of CCD eclipse minima timings by this observer. Here we present a total of 214 minima timings of 195 eclipsing binaries acquired in the calendar year 2021.

### 2 Observations, Data Reduction and Analysis

Selection of targets was made possible by software *EB\_Min* (available at Nelson 2020a). This software makes use of the data in EB\_Elements5c.xls (also available at the same website) which lists parameters from some 8847 eclipsing systems (at last count) largely based on a database of some 5473 O-C files available at Nelson (2019, 2020b). *EB\_Min* generates a customized nightly ephemeris taking into account the observer's local horizon and user-defined obstructions. Choices were made to maximize the scientific value of the timings based on inspections of the latest O-C files.

- Observatory and Telescope:
  1. Mountain Ash Observatory (mao),  $53^{\circ}54'41.52''$  N,  $122^{\circ}47'23.82''$  W, elev 606 m.; 33 cm f/4.5 Newtonian on Paramount ME (German equatorial) mount
  2. Desert Blooms Observatory (DBO),  $31^{\circ}56'27.96''$  N,  $110^{\circ}15'25.14''$  W, elev. 1095 m; 40 cm f/6.8 Meade SCT telescope on Paramount Taurus 400 (fork) mount
- Detector and Filters (all provided a choice of B, V, Rc, Ic, clear filters):
  1. mao: SBIG ST-10XME camera, 2184 x 1472 pixels, each  $6.8 \mu\text{m}$ , FOV  $34.4' \times 23.2'$
  2. DBO: QSI 683 camera, 3326 x 2504 pixels, each  $5.4 \mu\text{m}$  (binned 2x2), FOV  $22.3' \times 16.8'$
- Method of data reduction: Differential photometry using MIRA by Mirametrics Inc.
- Method of minimum determination: A choice of six methods as implemented in software *Minima* available at Nelson (2013, 2020a). Among those available, and used

here are: digital tracing paper method, Kwee and van Woerden (1956), five-term Fourier fit, and sliding integrations.

### 3 Data analysis

As mentioned above, up to four methods were used to extract times of minima from light curves surrounding each minimum. Every effort was made to include at least the inflection points in the light curve (and more if possible). This involved runs of typically three hours or more in duration, as shorter runs that capture only the bottom of the curve produce inaccurate results.

For the data presented here, the assignment of errors took advantage of the fact that multiple determinations for each timing (i.e., by using the different algorithms) were available. The sample standard deviation of the values provides a starting point for the error estimate. However, it should be remembered that it represents only the statistical error, and it can be shown that the systematic error is at least as large. Therefore, for this observer, it is standard procedure to adopt double the sample standard deviation (or perhaps slightly larger) for the error estimate. At no time is an error of less than  $\pm 0.0001$  day quoted.

### 4 Results

Table 1 lists the minima estimates. Column 1 lists the GCVS star name (or if absent, the GSC name with the designation shortened to "G" to save space); column 2 lists the GCVS (or VSX) eclipsing type, columns 3 and 4 list the heliocentric minimum times and errors respectively; column 5 lists the minimum type (I signifies a primary minimum, while II signifies a secondary); column 6 lists the filter(s) used; column 7 lists the observatory, and the instruments used (see Section 2). In the case that multiple filters are listed (e.g., BVI in data line 13), that signifies that the data were part of a full light curve acquisition; hence it would have been clearly seen whether the minimum was a primary or secondary one. In other cases, the assignment (of I or II) was based on the best available eclipse elements (epoch and period) and may or may not be correct. Again, with the case of multiple filters listed, in almost all instances the differences in times between filters were deemed negligible and a single mean value was quoted. In the case of one timing (KU Aur on 2021-01-31) the differences between filters were not negligible and separate eclipse times are quoted. (But for an earlier timing for the same star, the differences between filters *were* negligible.) Lest there be a suggestion that *all* times of minima from the different filters should be listed separately, it is worthwhile pointing out the purpose of all these minimum determinations is to understand the period variation in each system. Multiple equal or near-equal values for the same minimum that one sees in the literature are basically a nuisance, as they do not further the understanding of period variation, and lead to longer tables with much duplication. Further, variations of minima between different filters will often be of interest only to observers gathering their own full light curve data, and they will have numerous examples of their own.

Table 1: Times of minima of eclipsing binaries

Readers are encouraged to make use of the O-C database at Nelson (2019, 2020b) which contains over 5400 Excel files for the latest elements, many of which will supersede those at VSX. Efforts are planned to reconcile any differences in elements between the two databases.

## Acknowledgements:

Thanks are due to Environment Canada for the website satellite views (see reference below) that were essential in predicting clear times for observing runs in this cloudy locale. Thanks, are also due to Attila Danko for his *Clear Sky Charts* (see below).

This research has made use of the SIMBAD database, operated at CDS, Strasbourg, France

The construction of the O-C database (Nelson 2019, 2020b) has benefited from, in part, the databases of Kreiner (2012), Kundera (2012) and Paschke & Brát (2012) whose long-time dedication is gratefully acknowledged.
